RAILROAD CAR HAVING COLD FORMED CENTER SILL

This is a continuing application of United States Continuation-In-Part Patent Application Serial Number 08/953,337 filed on October 17, 1997, which is a 5 continuation-in-part of United States Patent Application Serial No. 08/712,369 filed on September 11, 1996.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates, in general, to railroad 10 cars and, more specifically, to a cold formed center sill and its method of manufacture.

2. Summary of the Prior Art

The center sill is the primary structural member of the underframe of a railcar. It is subjected to the buff and draft forces created during operation of the railcar and normally extends as a continuous member along the length of the car body. In the past, center sills have possessed many different cross-sectional configurations depending on the type of railcar and other considerations. 15 Center sills have been in the shape of hat designs, C-sections and other configurations. Regardless of its particular shape, it is well known to form a center sill by welding a plurality of hot rolled flat pieces or hot rolled sections together as a unit along its substantial length. 20 The use of numerous welds to manufacture center sills presents several long-existing problems. Because numerous welds are needed, the reliance on this process to fabricate a finished center sill is inefficient from both a cost and productivity standpoint. The application of the welds 25 along the lengths of the pieces being joined as a center sill is labor-intensive and cannot attain high-speed production. In addition, the application of multiple welds heats the material being joined and results in heat distortion and warpage. Warpage creates deviations in the 30 straightness or acceptable tolerances of the center sill being formed. As a result, further physical steps are 35

needed to finish the welded center sill unit and conform it to acceptable tolerances in camber, sweep and twist to be suitable for use in a railroad car. Existing center sills are subject to crippling of the webs which requires thicker
5 cross sections at critical structural areas. Furthermore, hot rolled sections do not always result in the desired tolerances for the finished camber of the sill. As an additional important consideration, a welded center sill is an inherently heavy structure due to its design and
10 fabrication technique. Accordingly, it is desirable in the prior art to provide an improved, lightweight center sill in which the necessity of a plurality of welds or other securement techniques are eliminated.

SUMMARY OF THE INVENTION

15 It is an objective of this invention to provide an improved center sill capable of being cold formed into a straight member having close tolerances. The various configurations of the several embodiments of the invention are cold formed at a plurality of cold rolling stations
20 from a plate or sheet of coiled steel. The flat sheet undergoes progressive formation at each rolling station whereby drawings of the steps of shaping developed by each roll station, when superimposed, form a flower diagram to assist the roll tooling designer. The center sills herein
25 disclosed can be formed on a continuous basis without interruption between separate center sills. One unique cold forming process of the invention allows center sills having a thickness up to 5/8 inch to be formed without the use of welds as in the prior art. Because the bent
30 sections forming the shape of the center sill are cold worked numerous times during working, the material is strengthened to resist crippling and produce a stronger cross section without thicker sections or reinforcing

material. The center sills are open at the bottom to provide desired access within the center sill body. Some of the configurations of the center sill include extra structural features that provide enhanced strength characteristics without adding a significant weight.

A complete understanding of the invention will be obtained from the following description when taken in connection with the accompanying drawing figures wherein like reference characters identify like parts throughout.

10 BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a side elevational view, with parts in section, showing any of the center sill embodiments of the invention on a railcar;

15 Fig. 2 is a cross-sectional view of a first embodiment of a single piece center sill for use with a railroad car such as illustrated in Fig. 1;

Fig. 3 is a cross-sectional view of a second embodiment of the single piece continuous center sill invention for use with a railroad car such as illustrated in Fig. 1;

20 Fig. 4 is a cross-sectional view of a third embodiment of the single piece center sill of the invention for use with a railroad car such as illustrated Fig. 1;

Fig. 5 is a schematic diagram of the cold forming apparatus for forming the cold formed center sill of the several embodiments of the invention; and

25 Fig. 6 is a cross-sectional view of a fourth embodiment of the cold formed center sill of the invention for use with a railroad car such as illustrated in Fig. 1.

30 DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring to Fig. 1, there is illustrated a railroad gondola car 2 for carrying commodities such as coal, gravel and the like and having an underbody carried

by opposed truck assemblies 4. The underbody of the railroad car of the invention includes a continuous single piece center sill 6 extending substantially the entire length of the car. A railcar body 7 is attached to the 5 underframe. As will be apparent from the following description, the single piece center sills of several embodiments of the invention provide significant advantages over prior center sills and contribute to a lightweight, economical car design. Although the center sills of the 10 invention are shown with reference to the gondola car of Fig. 1 by way of illustration, it is within the scope of the invention to use the single or the two-piece center sill herein disclosed with any type or design of rail freight car in which the advantages of the invention are 15 desired.

Referring now to Fig. 2, there is illustrated the first embodiment of the single piece center sill of the invention, generally designated by reference numeral 6a. The center sill 6a of Fig. 2 is formed from a suitable 20 steel by a cold rolling process to be described. The center sill 6a is formed in a generally rectangular configuration from a flat one-piece plate or coiled sheet of steel and is continuous along its length. The center sill is formed by bent sections created in the cold forming 25 process from a material having a thickness of up to 5/8 inch with thicknesses of either 3/8 inch to 5/8 inch being preferable. The center sill 6a includes an upper flat top wall 10 and a pair of flat side sections or webs 12, each of generally constant thicknesses.

30 The top wall 10 and pair of side sections 12 are joined together at right angles by upper curved sections 14 having curved outer surfaces 14a and curved inner surfaces 14b, the latter being formed about a common radius such as,

for example, 15/16 inch. The bottom sections 16 of the center sill 6a are inwardly formed horizontally at right angles to the side sections 12 through curved connecting sections 18 having curved outer surfaces 18a and curved
5 inner surfaces 18b, the latter being of constant radius such as, for example, approximately 15/16 inch. The bottom sections 16 terminate with a free end 20 to form a longitudinal opening 22 through which access within the center sill 6a is provided. By way of example, the bottom
10 sections 16 forming the bottom portions of the center sill may each extend approximately 4 inches from the side sections 12 and create the bottom opening 22 having a width of approximately 5 to 6 inches. The center sill 6a preferably possesses an average yield strength throughout
15 its length of at least 70,000 PSI and an average tensile strength of at least 80,000 PSI to easily meet all strength requirements for the center sill, but these values may be as low as 50,000 PSI and 65,000 PSI, respectively. The curved sections 14 and 18 are cold worked numerous times
20 during the cold rolling process. As a result, the material is cold hardened and strengthened at sections 14 and 18 as compared to its original unformed state. The resulting cross section does not require thicker sections or added material as in the prior art and provides a lightweight,
25 high-strength member.

Referring to Fig. 3, there is illustrated the second embodiment of the center sill of the invention. The center sill 6b of Fig. 3 includes upper top wall 30, opposite side sections or webs 32 and bent in bottom
30 portions 34 creating opening 35. The top walls 30, opposed side sections 32 and bottom portions 34 are respectively interconnected by upper curved sections 36 and lower curved sections 38 having a similar configuration as the

embodiment of Fig. 3. As in the prior art, the curved sections 36 and 38 are cold hardened during rolling for increased strength. The center sill 6b further includes a pair of upright internal flange portions 40 extending upward and being joined to bottom portions 34 by curved sections 42 of constant radius similar as curved sections 36 and 38. The center sill 6b is cold formed in progressive steps as the previous embodiment to obtain its configuration, but initially from a wider sheet or plate

5 material. The curved sections 42 are also cold hardened during rolling for increased strength. As a result, the cross section of the center sill 6b includes more material for similar external dimensions than the configuration of the embodiment of Fig. 2 because of flange portions 40 to

10 provide greater strength characteristics and high resistance to buckling, with only a minimum increase in weight. The thickness of center sill of Fig. 3 is preferably up to 5/8 inch, with 3/8 to 5/8 inch being preferred. The configuration exceeds the strength

15 20 characteristics of the preceding embodiment for the same dimensions and material and is also continuously formed from a one-piece coiled sheet or plate.

Referring now to Fig. 4, there is illustrated the third embodiment of the invention, generally designated by reference numeral 6c. The configuration of the center sill 6c is also similar to the embodiment of Fig. 2, but further includes a pair of inwardly disposed ribs 50 rolled out of the two side sections for webs 52 of the center sill 6c. The inwardly directed ribs 50 serve as stiffeners for the elongated center sill and are cold formed during the first stations in the rolling process. The center sill 6c includes a top wall 54 which is oriented at 90° to side sections 52 by a curved portion 55 having an approximate

radius, for example, of 15/16 inch and the like. The ribs 52 include inwardly extending connecting portion 56 of a length less than an inch and have a flat internal wall 57 to rigidize the center sill. The connecting portions 56
5 are also worked hardened as are curved portions 55. The bottom of the center sill includes a pair of partial horizontal bottom sections 58 integral to side sections 52 by curved sections 59. The bottom sections define longitudinal bottom opening 60 along the center sill 6c.
10 Although other sizes and dimensions may be employed in accordance with the invention, the center sill 6c may have a width of approximately 1 foot, 13/16 inch and a height of approximately 1 foot, 15/16 inch and the like. The embodiments described with reference to Figs. 2 and 3 may
15 have similar or external dimensions. The internal wall 60 of the ribs 50 may extend for a height of 3 to 4 inches or other suitable dimension. The bottom sections 58 may extend for approximately 4 inches at the bottom. The center sill 6c may be cold formed from a steel having a
20 preferable tensile strength of 70 KSI, but also as low as 50 KSI. Center sill 6c provides additional yield strength due to the presence of the stiffening ribs 50 for the same size and material as compared to the embodiment of Fig. 2, but only adds minimal weight to the overall structure of
25 the beam.

Referring now to Fig. 5, a schematic view of the technique of cold rolling the various embodiments of the center sill of the invention is illustrated. Coiled steel in sheet form is carried by a conventional uncoiler 70. In
30 the embodiment of Fig. 2, the width of the coiled metal may be, for example, 46 inches. As is well known, the stations of the rolling mill 74 comprise roll formers positioned at different orientations at each station to cause the

progressive deformation of the sheet material into the desired configuration. During the initial setup of the process, the steel coil is opened and fed through a flattener apparatus 72 to remove coil set. The lead end of
5 the coil is trimmed and joined to the trailing end of the previous length of material in a shear welder. The plate or sheet material is fed to a forming mill 74 comprising 10 or more pairs of roll forming stations to progressively form the flat material into the finished shape as shown in
10 Figs. 2, 3 and 4.

In the formation of the embodiment of Fig. 2, the flat plate or sheet material undergoes bending at a plurality of stations, such as 10 or more, that create the final cold formed shape of the center sill of Fig. 2 to be
15 formed. In connection with the embodiment of Fig. 3, added stations are required for the first several steps to form the bent up internal flange portions 40. As to the embodiment of Fig. 4, the rib sections 50 are also formed during the first several steps of the rolling process
20 during passage of the sheet material through the rolling mill 74.

After the final station in rolling mill 74 is passed, the formed single piece center sill is delivered to a cutoff press 76 which cuts the center sill to the desired
25 length without stopping the rolling process. The separated center sill then is conveyed to a conveyor 78 on which the profile of the center sill is inspected to determine whether its dimensions are correct and whether acceptable tolerances of camber, sweep and twist have been maintained.
30 The cold forming process of the invention attains significantly close tolerances in the final product of the center sill by a process that is capable of high production with minimum labor. This capability provides a vastly

superior product with economical manufacture and a beam structure of high quality and precise shape. The single piece center sill of the invention is lightweight, being approximately 1,000 pounds or more lighter than conventional welded sills.

Referring now to Fig. 6, there is illustrated a fourth embodiment of the present invention, generally designated by reference numeral 6d. The configuration of the center sill 6d is similar to the previous embodiments and includes a top wall 80 connected to a pair of side sections 82 through upper curved sections 84. Each side section 82 is connected to a bottom section 86 through lower curved sections 88. Each bottom section 86 terminates at a free end 90 forming a longitudinal opening 92 therebetween. The dimension of the center sill 6d is substantially the same as center sill 6a described above in connection with Fig. 2. The center sill 6d differs from center sill 6a by being formed of two separate cold formed halves connected by a single longitudinal weld 94. Fig. 6 also shows a bottom tie plate 96 and a bottom flange stiffener 98 attached to the center sill 6d which may be required on certain railcar designs.

The two-piece cold formed center sill 6d maintains many of the advantages of the one-piece embodiments 6a, 6b and 6c described above. The cold forming process provides sections with significantly less variance from the specified section than the prior art hot rolled sections. Additionally, the use of a single weld minimizes the assembly time associated with prior multi-weld configurations. The center sill 6d also exhibits a significant weight savings over the known prior art center sills. The two-piece center sill 6d is advantageous where the specific rolling mill 74 cannot accommodate the

complete center sill cross section. A rolling mill 74 may not contain enough stations to complete the entire cross section. In this case, the rolling mill can form two cold formed halves to form the center sill 6d of Fig. 5. The 5 cross sections of the center sills 6b and 6c shown in Figs. 3 and 4 may similarly be formed of two halves subsequently welded together.

Superior strength characteristics of the center sill of the invention are attained by using a steel such as 10 an ASTM A607, grade 70 or an ASTM A935, grade 70 for a plate or sheet having a thickness 3/8 inch. With a thicker sheet of material, such as 1/2 inch, an ASTM A607, grade 50 steel may be used with coiled plate or an ASTM A572, grade 50 with a coiled sheet. One suitable ASTM A607, grade 70 15 steel for thicknesses of 3/8 inch is known as Type 1, sold under the trademark Stelmax 70TM. Stelmax 70TM has an expected yield strength of 76 KSI and a tensile strength of 86 PSI. Other steels of the type described demonstrating similar properties may be used with the invention.

Some of the advantages of the present invention are highlighted with a comparison of the present invention with a standard center sill.

	3/8 Inch Thick One- Piece Center Sill	3/8 Inch Thick Two- Piece Center Sill 6b w/upturned flange	½ Inch Thick One- Piece Center Sill 6d w/o upturned flange	½ Inch Thick Two- Piece Center Sill 6d
Minimum Yield Point (KSI)	50	70	70	50
Minimum Tensile (KSI)	65	80	80	60
Weight Per Foot	82.4	60.2	56.5	80.0

Additionally, a 3K frame Bethgon Coalporter® railcar utilizing the center sill 3/8 Inch 6d was loaded to 286K gross rail load and standard AAR loads and load factors were applied. This was compared to the same type 5 of railcar utilizing a standard center sill. The margin of safety against yield failure of the material in the center sill was greater for center sill 6d.

The above comparison illustrates that the cold formed center sills of the present invention offer 10 significant advantages over the prior art center sills without detrimental drawbacks. It will be apparent to those of ordinary skill in the art that various changes may be made to the present invention without departing from the

spirit and scope thereof. Consequently, the present invention is intended to be defined by the appended claims.

WHAT IS CLAIMED IS:

1. A railcar comprising:
 - a plurality of truck assemblies, each truck assembly having at least one wheel;
 - an underbody supported on said truck assemblies,
- 5 said underbody including a cold formed center sill extending substantially the length of said railcar; and
- a railcar body attached to said underbody.
2. The railcar according to claim 1 wherein said center sill includes two cold formed sections and no more than one weld seam connecting said two cold formed sections.
3. The railcar according to claim 1 wherein said center sill includes a generally hollow rectangular configuration with an open bottom.
4. The railcar according to claim 3 wherein said center sill has a substantially uniform thickness of between about 3/8 inch to about 5/8 inch.
5. The railcar according to claim 3 wherein said center sill weighs less than 80 pounds per foot.
6. The railcar according to claim 1 wherein said center sill is formed of a single cold formed section without weld seams.
7. A gondola railcar comprising:
 - a pair of spaced truck assemblies, each truck assembly having four wheels; and

an underbody supported on said truck assemblies,
5 said underframe including a cold formed center sill, said
center sill comprising no more than two cold formed
sections, and no more than one weld seam connecting said
cold formed sections.

8. The gondola railcar of claim 7 wherein said
center sill is formed of a single cold formed section
without weld seams.

9. The gondola railcar of claim 8 wherein said
center sill includes a generally hollow rectangular
configuration with an open bottom.

10. The gondola railcar of claim 9 further
including at least one tub extending below said center sill
between said pair of truck assemblies.

11. The gondola railcar of claim 10 wherein said
center sill has a substantially uniform thickness of
between about 3/8 inch to about 5/8 inch.

12. The gondola railcar of claim 11 wherein said
center sill weighs less than 80 pounds per foot.

13. The gondola railcar of claim 7 wherein said
center sill has at least four work hardened corners.

14. The gondola railcar of claim 13 wherein said
center sill includes a pair of bottom wall portions, each
said bottom wall portion extending inwardly from one side
edge thereof.

15. The gondola railcar of claim 14 wherein said center sill is formed of a single cold formed section without weld seams.

16. The gondola railcar of claim 15 further including at least one tub extending below said center sill between said pair of truck assemblies.

17. The gondola railcar of claim 16 wherein said center sill includes a generally hollow rectangular configuration with an open bottom.

18. The gondola railcar of claim 7 wherein said center sill includes two cold formed sections and no more than one weld seam connecting said two cold formed sections.

19. The gondola railcar of claim 18 wherein said center sill has at least four work hardened corners.

20. The gondola railcar of claim 19 further including at least one tub extending below said center sill between said pair of truck assemblies.

RAILROAD CAR HAVING COLD FORMED CENTER SILL

ABSTRACT OF THE DISCLOSURE

A railroad car having a center sill formed by cold rolling a flat sheet of steel into a rectangular configuration. One of the embodiments includes strengthening flanges and another includes ribs. The cold formed center sill may be formed of a single cold formed section or a pair of cold formed sections joined by a single longitudinal weld seam.
